This bibliography was prepared from NTIS's on-line interactive bibliographic retrieval system consisting of more than 360,000 records of documents. These documents, dating back to 1964, were submitted to NTIS by all major Departments and Agencies within the Federal Government, as well as leading private organizations or individuals with Federal grants and contracts. Examples of document sources include the Departments of Defense, Housing and Urban Development (HUD), the Environmental Protection Agency (EPA), Booz-Allen, TRW Systems Group, Mitre Corporation, Massachusetts Institute of Technology, Sandia Labs, and the RAND Corporation. Each citation indicates the availability of the document and when available from NTIS quotes the price. Special order forms are available at the end of this bibliography.

MICROFICHE PRICE INCREASE

Many of the microfiche announced in these abstracts are priced at \$0.65 or \$0.95. However, due to the high cost of handling individual requests for microfiche, we have found it necessary to raise our price for this service. Effective August 16, 1973, the price for a report in microfiche will be \$1.45 for domestic orders and from \$2.45 to \$2.95 for foreign orders, unless announced at a higher price. Microfiche announced at a price higher than \$1.45 will continue to be sold at the announced price. The \$1.50 added charge for foreign orders continues to apply. Deposit Account holders will be charged for the increased price automatically. The price charged will be reflected on the monthly statement.

If your organization regularly places individual orders for microfiche in specialized subject areas, we suggest that you place a standard order for microfiche through our SCIM (Selected Categories in Microfiche) services. You can inquire about SCIM by writing the NTISearch Program at NTIS, or you may telephone your NTISearch analyst at (703) 451-0560.

Base Food Chain Relationships in Coastal Salt Marsh Ecosystems

Lehigh Univ., Bethlehem, Pa. (205 450)

Completion rept. 21 Nov 69-31 Mar 71

AUTHOR: Brickman, Laurence Michael

C1551L1 FLD: 6F, 57H, 86Q USGRDR7320

1972 189p

GRANT: NMFS-3-114-R

Doctoral thesis. Sponsored in part by New Jersey Dept. of Environmental Protection, Trenton. Div. of Fish, Game and Shellfisheries.

ABSTRACT: The distribution and abundance of the meiobenthos was studied monthly from October 1969 to December 1970 at six stations within the Dividing Creek watershed in Cumberland County, New Jersey. The total number of individuals ranged from 36-10,594/10sqcm and the dry weight biomass from 0.62-17.59mg/10sqcm. Free living nematodes which comprised 78.3% of the total numbers and 62.3% of the biomass were the most abundant organisms collected at all but the stations located in the middle and upper reaches of Dividing Creek. Harpacticoid copepods were second in overall abundance, comprising 14.8% of the total numbers and 14.7% of the total biomass, and were the most abundant organism at the remaining two stations. (Modified author abstract)

ABSTRACT: The dynamics of estuaries of the Gulf of Mexico bordering Mississippi are described in four phases. Phase I, Area Description, reviews the history and evolution of Mississippi estuaries and depicts the prevailing environmental conditions and economic development along the Mississippi coast. Phase II, Hydrology, presents data on the physico-chemical water quality of estuaries and describes the seasonal and areal variations. Phase III, Sedimentology, describes the composition and grain size of sediments in Mississippi Sound and adjoining bays and streams. Phase IV, Biology, identifies and quantifies the flora and fauna of Mississippi estuaries and describes their associations. Floral descriptions include the marsh grasses and emergent and submergent aquatic vegetation. Faunal descriptions include estuarine zooplankton, invertebrates and vertebrates. (Author)

ABSTRACT: Using the bicounty Nassau-Suffolk region of Long Island as a case study, it was found that the natural resources and resource-use processes of the estuarine zone could be conceptually related in a 'system'. This ecosystem and its interrelationships were specifically displayed in a matrix form so that planning analysis for management decisions could be accomplished. Visually, the twenty-one important processes occurring in the physical, biological, resource-use (market) and socio-economic sectors of the system have been related. The effect of an increase in any one process on all of the others has been indicated in a directional sense as causing an increase, decrease, no effect or countervailing effect. The implication of these effects for planning future activities has been discussed. Emphasized in this study are: fish and shellfish, sand and gravel, waterfront land for housing and commercial development, dredging, erosion, recreational activities including boating, fishing, and swimming, park development, pesticide application and waste discharge. (Modified author abstract)

DESCRIPTORS: (*Natural resources, Management planning), (*Long Island, Land development), (*Land development, Natural resources), (*Estuaries, Land development), Ecology, Water pollution, Dredging, Decision making, Recreation, Pesticides, Erosion, Swamps, Marine fishes, Shellfish, Mining, Matrix methods, Conflict

REPT NO: 81

CONTRACT: DI-14-31-0001-3315

ABSTRACT: Large areas of irregularly flooded North Carolina salt marsh dominated by *Juncus roemerianus* were ditched in an attempt to control mosquito breeding. Comparative study of ditched and unditched marshes at three locations in N.C., was carried out to determine the extent of ecological changes. Ditches increase the area of aquatic habitat in marshes by a factor of 5, are inhabited by large numbers of juvenile fishes, crabs, and shrimp, and increase the amount of nursery ground for fish and crustaceans. Animal variety in ditches is low. Oysters planted in the ditches do not grow well. It is unlikely that oysters or shrimp could be cultured successfully on a commercial basis in ditches. Marshes were flooded 10-28% of the time. Fiddler crabs were present on all marshes. During flood tides fishes occur on both ditched and unditched marshes. Brushy vegetation invaded many spoil piles and along ditches. Invasion continued during the two year study. Failure of vegetation to significantly cover many spoil piles after eight years, and continuing erosion of spoil piles to form water-retaining levees along ditches is cause for concern.

DESCRIPTORS: (*Ditches, *Ecology), (*Insect control, Ditches), (*Estuaries, Ecology), Swamps, Soil erosion, Aquatic biology, Drainage, Culicidae, North Carolina

Summaries in French and Spanish.

Pub. in Marine Pollution and Sea Life, p1-7 Dec 72.

ABSTRACT: Studies were conducted during 1969 to compare the ecology of a natural estuarine area (Marsh and bay) with the ecology of an adjacent estuarine area altered by channelization, bulkheading, and filling. In each area, hydrographic factors, fishes, crustaceans, and benthic macro-invertebrates were sampled. Setting, growth, and mortality rates of juvenile oysters were measured. In general, productivity was highest in the marsh, intermediate in the canals of the altered areas and lowest in the open bay. If the altered area is not self-supporting and if areas of marsh are developed in ways similar to the present, then biological productivity of the estuarine zone will be reduced in relation to the acres of marsh altered.

DESCRIPTORS: (*Biological surveys, Estuaries), (*Land development, *Estuaries), Land use, Swamps, Primary biological productivity, Invertebrates, Benthos, Dredging, Spoil, Channels (Waterways), Hydrology, Sediments, Phytoplankton, Oysters, Marine fishes, Seasonal variations, Ecology, Mexico Gulf, Water pollution

Monitoring Toxaphene Contamination in a Georgia Estuary

Georgia Marine Science Center, Savannah.

Technical rept. series

AUTHOR: Reimold, Robert J., Durant, Charles J.

C1085A1 FLD: 6F, 8A, 68E, 57H, 78A, 86M USGRDR7314

Nov 72 21p

REPT NO: TR-72-8

Prepared in cooperation with Skidaway Inst. of Oceanography, Savannah, Ga.

ABSTRACT: In this study efforts were made to quantify the flux of toxaphene through the salt marsh cordgrass *Spartina alterniflora*, to consider the species diversity of Terry Creek, and to evaluate toxaphene concentrations in selected fauna and flora. It was found that there was a significant increase in species diversity in the Creek during the past two years. In general it appears that there was a significant decrease in toxaphene levels from 1970-1971 to 1971-1972.

ERTS-1 Data User Investigation of Wetlands Ecology

American Univ., Washington, D.C. Dept. of Biology.

Progress rept. no. 5

AUTHOR: Anderson, Richard R.

C0852E1 FLD: 8H, 93A USGRDR7312

16 Apr 73 5p

CONTRACT: NAS5-21752

ABSTRACT: The author has identified the following significant results. ERTS-1 imagery (enlarged to 1:250,000) is an excellent tool by which large area coastal marshland mapping may be undertaken. If states can sacrifice some accuracy (amount unknown at this time) in placing of boundary lines, the techniques may be used to do the following: (1) estimate extent of man's impact on marshes by ditching and lagooning and accelerated successional trends; (2) place boundaries between wetland and upland and hence estimate amount of coastal marshland remaining in the state; (3) distinguish among relatively large zones of various plant species including high and low growth *S. alterniflora*, *J. roemerianus*, and *S. cynosuroides* and (4) estimate marsh plant species productivity when ground based information is available. Paper copy available from GPO \$1.75 as EP2.25:9.

ABSTRACT: In the northeastern United States the mosquito abatement programs are conducted for the vector control of Eastern equine encephalitis, to reduce the nuisance problem caused by mosquitoes, and to enhance recreation areas. Typically, these programs consist of the application of pesticides (vectoricides) and the drainage of stagnant water. The report summarizes a case study of a specific vectoricide use situation documenting the kinds and quantities used, their route from the point of initial application into the water environment, their ultimate effect on the ecosystem, and the laws and regulations which affect their use. Cape Cod was chosen for the study area.

Fatty-Acid Ecology of a Tidal Marsh

Rhode Island Univ., Kingston. Graduate School of Oceanography. (406 099)

AUTHOR: Jeffries, H. Perry

C0695E4 FLD: 8H, 6F, 6A, 64H, 57H, 57B, 86M USGRDR7310

1972 9p

Pub. in Limnology and Oceanography, v17 n3 p433-440 May 72.

ABSTRACT: A salt marsh has differing biochemical patterns: The grasses have a terrestrial pattern rich in 16-18 C fatty acids, the animals a marine pattern dominated by long-chain polyunsaturates. The patterns vary, but they remain far more distinct than at corresponding positions in the structure of an offshore community. Each pattern is reflected in the diet of two species of marsh fishes. Their most probable diet is a mixture of 5 parts detritus to 1 part marine invertebrates. This ratio is also a boundary condition: It cannot go any higher and still account for the patterns occurring in the digestive tracts. Food is so abundant during spring that despite identical diets the two species could avoid competition. (Author)

DESCRIPTORS: (*Ecology, Swamps), (*Swamps, *Biochemistry), (*Fatty acids, Swamps), Grasses, Aquatic animals, Fishes, Diets, Limnology, Water chemistry, Lipids

Color-Infrared Aerial Photographic Interpretation and Net Primary Productivity of a Regularly Flooded North Carolina Salt Marsh

North Carolina Water Resources Research Inst., Raleigh.

AUTHOR: Stroud, Linda M., Cooper, Arthur W.

C041512 FLD: 6F USGRDR7306

Nov 68 100p

REPT NO: 14

CONTRACT: DI-14-01-0001-978

ABSTRACT: A study was made of net primary productivity of salt marsh communities in a 2000-acre, regularly flooded marsh in Brunswick County, North Carolina. Color infra-red aerial photographs were used to determine acreages of community types. Net primary productivity estimates were based on harvest method data. Observed harvest data were fitted to a fourth degree polynomial in time in order to express the average behavior of the standing crop through the year. Net productivity was determined by two methods: Use of living standing crop only, and Use of changes in living and dead standing crop. Over the entire marsh net primary productivity was estimated to be 1534 kcal/m sq/yr. These values were lower than similar values from Georgia but resembled closely other estimates of net primary productivity for salt marsh vascular plants in North Carolina.

DESCRIPTORS: (*Swamps, *Primary biological productivity), (*Aerial photography, Primary Biological productivity), Estuaries, Infrared photography, Coasts, Tide water, Grasses, Ecology, Color photography, Salt water

AUTHOR: Anderson, Richard B., Carter, Virginia, McGinness, John W. Jr

CO201H2 FLD: 93A USGRDR7303

Nov 72 11p

CONTRACT: NAS5-21752

ABSTRACT: The author has identified the following significant results. The ERTS imagery analyzed provides approximately 2/3 coverage of the test site. Analysis was made using visual methods, density slicing, and multispectral analysis. Preliminary conclusions reached are that most, if not all, of the investigation objectives can be met. Saline and near-saline wetlands can be delineated from ERTS-1 images as the wetland-upland boundaries and land-water interface are clearly defined. Major plant species or communities such as *Spartina alterniflora* (high and low vigor forms), *Spartina patens*/*Distichlis spicata*, and *Juncus roemarianus* can be discriminated and spoil disposal areas identified. Observations on 'Claviceps purpurea' on 'Spartina alterniflora' in the Coastal Marshes of Mississippi

Gulf Coast Research Lab., Ocean Springs, Miss. (159 970)

AUTHOR: Eleuterius, Lionel N.

A5294C4 FLD: 6M, 57K, 57C, 86Q USGRDR7222

1970 6p

GRANT: NMFS-2-25-R

Pub. in Gulf Research Reports, v3 n1 p105-109 Sep 70.

ABSTRACT: The fungus *Claviceps purpurea* was observed on the oyster grass *Spartina alterniflora* during the late summer and fall of 1968. List-count quadrats are used to obtain data on the intensity of the infection. *C. purpurea* was present on 96.5% of the mature culms. Seventy-one percent of the seed produced on infected panicles bore sclerotia. It is estimated that the fungus reduced the total potential production of viable seeds by 58.5% during 1968. The importance of *S. alterniflora* in reducing erosion in the estuarine environment makes this infection a serious detriment to environmental protection.

Insect Pest Management in Coastal and Estuarine Habitats

North Carolina State Univ., Raleigh. Dept. of Entomology. (406 314)

Summary rept.

AUTHOR: Axtell, R. C., Knight, K. L.

A4331F1 FLD: 6F, 57P, 86M USGRDR7212

31 Dec 71 58p*

GRANT: NSF-GH-78

ABSTRACT: The extreme ecological importance of coastal and estuarine zone makes it essential that the populations of insect pests be managed by methods that are compatible with the estuarine ecosystem. Ecologically sound insect control in this situation requires the judicious meshing of chemical, cultural, and biological methods into a program of pest management. The objective is to lower the mean level of abundance of an entire pest population by methods or a combination of methods which supplement the natural control agents, give long term alleviation of the problem, and cause the least disruption of the ecosystem. It is based on the realization that natural pest populations cannot be eliminated; rather they must be managed so that they occur at tolerable levels.

ABSTRACT: Computer simulation, laboratory experiments and field measurements were integrated to determine the dynamics of growth of mixed populations of bacteria associated with the marsh grass, *Spartina alterniflora*. Simulation was useful in optimizing the design of the laboratory experiments which in turn provided empirical values for updating the model. Both theoretical considerations, as elucidated by simulation of the system, and laboratory results were useful in determining the ecologically significant parameters for verification, and also in completing the dynamics of the system as a whole in those areas where direct field determinations were difficult or impossible. Modeling and simulation provide subunits that are in a form which may be integrated with an overall system even before complete investigation and refinement of the individual unit.

Report on Sea Grant Program (Estuarine and Coastal Studies).

ABSTRACT: Growing realization of the highly fertile nature of estuaries and coastal marshes has been accompanied by more active consideration of the mechanisms by which this high productivity is maintained. It has become evident that in many instances plant detritus, often of allochthonous origin, is at least in part responsible. Since the estuarine regions of Everglades National Park are dominated by dense mangrove forests, it is important to investigate the role played by mangroves in the productivity of the area. The study, conducted on the North River from 1967 to 1969, is an attempt to delineate and quantify the mechanisms and pathways by which dead plant material, particularly that of red mangroves, becomes incorporated into the aquatic system and thereby constitutes an important energy source.

Report on Sea Grant Program (Living Resources).

ABSTRACT: The annual contribution of mangrove forests to the ecosystem solely from leaf fall exceeds three tons (dry wt.) per acre. This leaf fall when converted by bacterial and fungal action into detritus particles supports a large population of detritus consumers both in the vicinity of the mangrove forest and in surrounding coastal waters. The detritus consumers, in turn, provide food for organisms at higher trophic levels such as gamefishes and wading birds. The permanent removal of large numbers of mangroves from an estuary will reduce the annual production of organic detritus in that estuary; ultimately, this will limit the population size of detritus consumers and reduce the numbers of animals at higher trophic levels which are of interest to man from a commercial and recreational standpoint.

Smith Island: A Resource Capability Study

North Carolina Univ., Wilmington, Dept. of Biology.

Interim rept.

AUTHOR: Parnell, James F., Adams, David A.

A2595F4 FLD: 6F, 52I, 86M USGRDR7117

Apr 70 91p

ABSTRACT: In recent years, developers have focussed their attention on Smith Island and several plans have been put forth to transform it into a coastal resort community. Alternate proposals have been made to retain the island in a more natural state and in some form of public ownership. This project was designed to study the ecology of the island complex and to evaluate the effect of man on the island. This interim report is based on the first one-half year of study. (NOAA-OSG abstract)

REPT NO: RM-509J

Presented at the International Symposium on Remote Sensing of Environment (7th), 17-21 May 71, Ann Arbor, Mica.

ABSTRACT: Precision automated photometric mapping of wetlands in Calvert County, Maryland has been achieved in an operational system as the result of a program including aerial color film (both true color and false color infrared) calibration and control. Although the system was operated over this area, it may be adapted to other areas. The recognition appears to be most accurately achieved by microdensitometric analysis of the true color transparency in a narrow band centered in the red (0.633 millimicrons), on 3000-foot altitude imagery. A computer generated map is obtained. (Author)

GRANT: NSF-GH-101

Report on Sea Grant Program.

ABSTRACT: A survey was conducted to identify the macro-fauna of a marsh adjacent to West Galveston Bay, Texas. The factors affecting their distribution were studied for evaluation of changes which might result from large areas of marsh being impounded for shrimp culture. Results indicate that construction of large-scale impoundments for shrimp culture, at the expense of removing flooded grasslands, would alter the physical features of the marsh and reduce habitats suitable for year-round survival of the stable macro-fauna. In addition, competitor and predator control in these ponds would require the removal of all aquatic macro-fauna other than shrimp. The impact of these changes on the total marsh ecosystem is not known but should be considered and studied in detail before ponds are constructed. Conceivably, marsh areas could be managed so as to insure a reasonable amount of habitat for the stable macro-fauna while allowing ample lands for shrimp culture. (TAMU-SG abstract)

ABSTRACT: 'Die-back' is a term applied to degeneration and death of large areas of *Spartina townsendii* marshes in England. What appears to be the same condition affects *S. alterniflora* marshes in Louisiana and possibly elsewhere in North America. Several factors are likely to be involved and should be assessed in future work. These include (1) excess salinity, (2) pathogenic organisms, (3) lack of available iron, (4) hydrogen sulfide toxicity, (5) change of tidal regime, and (6) pollution. It is especially important that the effects of pollution and alteration of tidal regime through dredging be investigated. (Author)

ORO-3238-7 CFSTI Prices: HC\$6.00 MF\$0.95

ABSTRACT: During the 1969 contract year the flux of ^{32}P from the sediments through Spartina alterniflora, and its subsequent release into the salt marsh ecosystem were evaluated. Related field experiments have been concerned with the flux of ^{32}P , ^{65}Zn , ^{90}Sr , and ^{59}Fe through the five compartments identified in our mathematical model. Mathematical modeling efforts have been directed toward digital, analog, and digital-analog hybrid computer solutions as well as analytical solutions. Effects of inputs and outputs in the five compartment model have been considered as well as the effect of perturbations of the standing stock values. The model appears to respond closely to natural environmental measurements and consequently can be expanded in complexity to include a greater number of compartments and non-linear flux rates. ABSTRACT: Several foraminiferal assemblages are recognized in Spartina-Salicornia marshes along the Pacific and Gulf of Mexico coasts. Continuous recordings in one Pacific marsh show considerable diurnal and seasonal variation in pH, oxygen, water temperature, and salinity. This is related to tidal flushing, air temperature variations, sunlight duration, and marsh plant metabolism.

CONTRACT: Nonr-2216(23)

Availability: Published in Limnology and Oceanography v10 suppl
PR169-84 Nov 1965.

ABSTRACT: Populations of living Foraminifera were studied from six areas of marine marsh in Galveston Bay. The general marsh foraminiferal assemblage is an *Ammonium salsum*-*Miliammina fusca* one, with common *Ammonia beccarii*, *Arenoparrella mexicana*, and *Trochammina inflata*, and also containing *Ammonia* *inaepta*, *Elphidium* spp., *Trochammina* *comprimata*, and *Trochammina* *macrescens* in somewhat smaller frequencies. The following marsh environments have distinctive assemblages of Foraminifera; (1) channel or bay bordering a marsh, (2) fringing *Spartina* zone, (3) *Salicornia* berm, (4) inner *Spartina* zone, (5) inner *Salicornia* zone, (6) lagoon barrier marsh, (7) more saline marsh, and (8) less saline marsh. Living populations are very small to very large, living-total population rates are large and deposition rates are high. Extreme range of environmental conditions limits the variety of marsh Foraminifera. Knowledge of the environment is inadequate to explain distributions within the marsh. (Author)

DESCRIPTORS: (*Foraminifera, Swamps), Ecology, Bays, Beaches, Texas
